Powering the Future: AI Across Healthcare, Energy, and Transportation

Artificial Intelligence is no longer confined to labs or experimental use — it is actively transforming how industries operate, make decisions, and deliver value. From hospitals improving patient care, to data centers solving the electricity crisis powering AI itself, to self-driving cars navigating city streets without a human behind the wheel — AI is driving measurable, real-world impact across every sector it touches.

Industries covered in this edition

- **Healthcare** — AI voice assistants and real-time patient monitoring transforming care delivery (ElevenLabs)
- **Energy & Infrastructure** — Chip-to-grid AI power platforms solving the data center electricity crisis (Claros)
- **Transportation** — Autonomous vehicles reshaping mobility economics and business decision-making (Waymo)

INDUSTRY 01 · HEALTHCARE

Healthcare AI: Smarter Care Through Voice & Real-Time Monitoring

AI-powered voice assistants and connected health devices are transforming how healthcare providers interact with patients and deliver care. These technologies automate routine tasks while enabling continuous monitoring and faster clinical decisions — addressing two of healthcare's most persistent challenges: staff workload and response time.

Company spotlight

ElevenLabs — leading the AI voice revolution in healthcare

ElevenLabs is an AI voice technology company whose platform enables healthcare organizations to build and deploy intelligent voice assistants capable of holding natural, human-like conversations in over 70 languages. In healthcare settings, patients can interact with an AI assistant after hours, have their symptoms evaluated, and have appointments scheduled instantly — without a human operator.

communication

2,000%

Revenue growth from 2023 to
2025

Real-world use case

A patient calling after hours is greeted by an AI voice assistant that asks targeted questions, evaluates symptoms, and either schedules an appointment or escalates to emergency care. Connected medical devices simultaneously monitor vitals and alert clinical staff when intervention is needed — all without a human dispatcher. In large organizations like CVS Health, this streamlines high-volume interactions and pharmacy workflows at scale.

Impact on business processes

- **Reduced administrative workload** — routine scheduling, triage, and follow-up calls no longer require human staff time
- **24/7 patient availability** — AI handles interactions around the clock without staffing constraints
- **Faster clinical decisions** — real-time monitoring data surfaces alerts before a condition escalates
- **Improved patient outcomes** — early AI-driven intervention reduces avoidable complications

ElevenLabs — key growth metrics

Future potential

Healthcare is moving toward fully integrated AI ecosystems where voice assistants, monitoring devices, and pharmacy systems work together to deliver proactive, personalized care. ElevenLabs — now valued at \$11 billion — is poised to become standard infrastructure across every major health system.

Energy AI: Solving the Electricity Crisis Inside Every AI Data Center

Everyone talks about how AI is getting smarter and faster. But there is a physical limit almost nobody discusses: the power getting to the chip. Right now, up to 40% of the electricity sent into a data center never reaches the processor — it bleeds away as heat. As AI data centers are projected to consume 8% of all U.S. electricity by 2030, fixing this is no longer optional.

Company spotlight

Claros — chip-to-grid AI power platform · \$30M seed round closed March 19, 2026

Founded in 2024 by Daniel Kultran and Grant Verstandig out of Red Cell Partners, Claros is redesigning how electricity travels from the power grid to the processor. Their approach: eliminate the cascade of AC-to-DC conversions that waste energy at every step, and move power regulation physically closer to — or directly beneath — the chip itself. Just three days ago, they closed a \$30 million oversubscribed seed round co-led by General Catalyst and Red Cell Partners.

Reduction in power loss vs. legacy systems

3

Physical chip designs built and on test bench in LA

Two products transforming data center architecture

Product 1 — The Integrated Voltage Regulator (IVR)

Today, voltage regulators sit on a separate board, several inches from the chip. Claros places the regulator directly beneath the chip — shrinking power delivery distance from inches to millimeters. That single change reduces power loss by 30%. One module handles 40 amps; the architecture scales to 40,000 amps — from a small edge server to a hyperscale facility running thousands of GPUs.

Product 2 — The Power Gateway

The Power Gateway replaces the entire chain of AC-to-DC conversions that a traditional data center requires. It takes power from any source — grid, solar, or battery — and outputs clean, stable DC in one step. Legacy systems require 8 conversion steps before power reaches a chip. The Claros architecture reduces that to 5, with the final step measured in millimeters via the IVR. The demo unit is already assembled; manufacturing targets 2027.

Power loss comparison — legacy vs. Claros IVR vs. theoretical minimum

Source: Claros technical brief · AI Pulse research (Mar 2026)

Impact on business processes and decision-making

- **Lower operating costs** — a 30% efficiency gain in a 100-megawatt data center translates to tens of millions in annual savings
- **Faster data center deployment** — DC-native architecture eliminates conversion infrastructure, cutting build time by 6–12 months
- **Renewable energy compatibility** — solar and battery systems output DC directly, making green data centers architecturally simpler
- **Grid stability** — more efficient power delivery reduces total draw from an already strained national electricity grid

Future potential

AI data centers are projected to consume 1,000 terawatt-hours of electricity by 2030 — roughly equivalent to Japan's entire annual electricity consumption today. Claros is betting that the company who solves how electricity physically reaches the chip will be as foundational as the chip companies themselves. With IVR engineering samples going to customers in 2027 and Power Gateway manufacturing launching the same year, the commercial roadmap is in motion.

INDUSTRY 03 · TRANSPORTATION

No Driver Needed: How Waymo Is Rewriting Transportation

Of all the ways AI is transforming transportation, none is more visible than autonomous vehicles. Waymo — Google's self-driving subsidiary under Alphabet — has crossed from experiment to commercial reality, operating fully driverless robotaxis across ten U.S. cities with 170 million autonomous miles and zero serious crashes to date.

Company & product spotlight

Waymo and the Waymo Driver

Founded in 2009 as a Google project and spun off under Alphabet in 2016, Waymo operates the world's most commercially advanced autonomous vehicle service. The **Waymo Driver** fuses

cameras, LiDAR, radar, and HD maps in real time, making driving decisions in milliseconds using a foundation model trained on Google's Gemini AI. Its multi-sensor approach is what allowed Waymo to remove the human safety driver in 2020 — years ahead of competitors.

What makes Waymo different
No single point of failure can cause a bad decision. Its Vision Language Model handles rare scenarios — like recognizing a burning vehicle ahead and rerouting even when the lane appears technically clear. Every mile driven feeds back into continuous model improvement, creating a compounding safety and performance advantage.

170M+
Autonomous miles, zero serious crashes (Mar 2026)

400K+
Paid rides completed every week

91%
Fewer serious-injury crashes vs. human drivers

How Waymo transforms business processes

- **Restructuring economics** — human drivers account for 70–80% of every ride-hailing fare; Waymo eliminates that cost at scale with a projected cost-per-mile of \$0.25 by 2035 vs. \$2.00 today
- **Data-driven safety** — AI logs every mile and continuously improves, replacing reactive post-accident analysis with proactive model refinement
- **New business models** — Uber dispatch integration in Austin and Atlanta, DoorDash autonomous delivery in Phoenix, 1,000+ daily airport trips at Phoenix Sky Harbor

Recent updates

In February 2026, Waymo raised **\$16 billion at a \$126 billion valuation** and expanded to 10 active U.S. cities. On March 20, 2026 — just yesterday — it crossed **170 million fully autonomous miles with zero serious crashes**, the most comprehensive autonomous safety

dataset ever published. Over 20 cities including London and Tokyo are targeted for 2026.

Challenges to acknowledge

School bus incidents in Austin and Atlanta triggered federal investigations and a December 2025 software recall. A March 2026 incident in Austin where a Waymo blocked an ambulance near an emergency scene raised further edge-case concerns. The company is also not yet profitable — Alphabet expects financial returns from 2027–2028. These are real challenges, but they exist alongside a safety record that still dramatically outperforms human drivers.

What These Three Industries Tell Us About the AI Moment We Are In

Taken individually, ElevenLabs, Claros, and Waymo are three very different companies solving three very different problems. But viewed together, they reveal something more significant: AI is no longer optimizing processes at the edges of industries — it is restructuring the core of them.

A common pattern across all three

Each of the companies featured in this edition shares a defining characteristic: they are not building AI tools on top of existing systems. They are replacing the foundational assumptions those systems were built on.

- ElevenLabs does not improve the hospital phone system — it eliminates the need for a human to answer it
- Claros does not make traditional power delivery more efficient — it redesigns the physical path electricity takes to reach a chip
- Waymo does not make drivers safer — it removes the driver from the equation entirely

The infrastructure layer is where it gets interesting

One of the most underappreciated findings across these three sectors is how interconnected they are. Waymo's autonomous vehicles run on AI models that require enormous compute. That compute runs in data centers. Those data centers are consuming electricity at a pace the grid was never designed to handle. Claros is solving the efficiency problem at the physical layer that makes scaling all of this — including Waymo — possible. And ElevenLabs is demonstrating that the AI-driven interactions enabled by that infrastructure are already changing how people access healthcare, one of the most critical services in any economy.

In other words: ElevenLabs represents the application layer of AI. Waymo represents the physical-world deployment layer. And Claros represents the infrastructure layer that both depend on. Together, they form a complete picture of what a functioning AI economy looks like.

Where investment is concentrating — and why

Company scale comparison — valuation / total funding raised (2026)

Sources: Waymo, ElevenLabs, Claros public disclosures · Spring 2026

The funding gap between these three companies is enormous, but it reflects stage rather than importance. Waymo has been building since 2009 and is deploying commercial services today. ElevenLabs has scaled to an \$11 billion valuation in just a few years on the strength of an exploding voice AI market. Claros, just thirteen months old, closed an oversubscribed \$30 million seed round three days ago — which, for a deep-tech hardware company, signals serious institutional confidence in both the technology and the team.

What organizations should take away

The clearest lesson from all three industries is that the gap between AI adopters and non-adopters is widening faster than most organizations anticipate. Waymo's safety record is already statistically superior to human drivers. ElevenLabs is already handling patient interactions at healthcare organizations running hundreds of millions of customer touchpoints per year. Claros' technology, once in production in 2027, will be embedded in the data center infrastructure powering every serious AI workload going forward.

For decision-makers in any of these sectors, the question is no longer whether to engage with AI — it is whether your organization is building the understanding, the processes, and the partnerships to engage with it effectively before competitors do.

Conclusion

AI is transforming healthcare delivery, reinventing energy infrastructure, and rewriting the economics of transportation — simultaneously, and at accelerating speed. ElevenLabs, Claros, and Waymo each represent a different layer of this shift: the application, the infrastructure, and the physical world deployment. Understanding all three is essential for anyone navigating the industries they are reshaping.
